Treatments for Vitiligo (also known as Leukoderma):  
Vitiligo is a condition which is commonly misunderstood and under-treated. Vitiligo is not always a disease with associated symptoms. The condition is a permanent loss of pigmentation in the skin, resulting in white patches. It generally affects the skin around the eyes, nose and mouth (they're also referred to as "vitiligo calico"). It is not a form of albinism. Vitiligo is sometimes misunderstood as a skin disease affecting only the skin; however, it is not. It is a chronic autoimmune condition and can affect the whole body. Some examples of autoimmune conditions include lupus, insulin-dependent diabetes mellitus, multiple sclerosis, vitiligo, and rheumatoid arthritis. Treatments for Vitiligo Treatment for vitiligo often requires a combination of several treatments: -Sun protection – You should wear broad-spectrum sunscreen every time you are outdoors, regardless of the weather. Wear your sunscreen all day and before bedtime. -Avoiding the sun – In general, avoid the sun. It may be helpful to wear protective clothing such as wide-brimmed hats and long-sleeved shirts. If you are staying in the sun for long periods of time, it is best to use sunscreen and reapply often. -Diet – Check with your doctor if you have any health problems, particularly if you have diabetes, heart disease or high blood pressure. Vitiligo is also associated with celiac disease and Epstein-Barr virus. -Topical medications – Some people also find it helpful to use topical

---

medications. These can usually be purchased over the counter and can be used to lighten areas of vitiligo.

-Steroid injections – Some people experience symptomatic improvement with injections of steroids into the involved areas. Steroids come in different forms, such as creams, ointments, gels, and injections. -Skin tattooing – This is not recommended for most people. But some doctors may tattoo the areas of vitiligo, especially children. -Skin grafts – Often used to treat widespread vitiligo, skin grafts take a piece of healthy skin from one part of your body and place it over a white patch. The skin grafts can make the whiteness more even, but they are not a cure for

Anxiety and Avoidance Among Weight-Loss Participants Follow an Expanded Antecedent-Focused Intervention. Although research supports Expanded Antecedent-Focused Intervention (EA-Fi) as an efficacious psychological weight-loss treatment for those with eating-disordered psychopathology, only recent work has examined factors that can increase treatment success among participants with co-occurring eating-disordered psychopathology. The current study measured anxiety and avoidance, two factors considered important by EA-Fi users, among 40 weight-loss participants, 26 of whom were currently enrolled in EA-Fi. Participants showed substantial improvement on EA-Fi's effectiveness scales at posttreatment but not at 6-month follow-up, and they showed increases in anxiety and avoidance. Participants

who reported higher anxiety at preintervention were more likely to show improved effectiveness at posttreatment. There were no significant interactions between improvement on effectiveness scales and preintervention anxiety or avoidance. The current findings provide preliminary support for using preintervention anxiety and avoidance to predict weight-loss outcomes among EA-Fi participants.
